INTRODUCTION

This service manual was prepared for use by Authorized Warranty Stations and contains service data for the Marantz Model 28 Stereophonic Receiver with automatic turntable.

Servicing information and voltage data included in this manual are intended for use by knowledgeable and experienced technicians only. All instructions should be read carefully. No attempt should be made to proceed without a good understanding of the operation of the set. A brief functional description and associated block diagram, furnished in the Operating Instruction Manual for the Model 28 Receiver, provide functional data about the set as an aid in this understanding.

The parts list furnishes information by which replacement parts may be ordered from the Marantz Company. A description is included for parts which can usually be obtained through local suppliers.

No description for the associated Garrard synchro-Lab 55B Automatic Turntable is included in this service manual. A service manual for Garrard 55B published by the Garrard Engineering and Manufacturing Co., should be consulted to work on the automatic turntable.

1 . SERVICE NOTES

As can be seen from the circuit diagram, the chassis of the Model 28 consists of the following units. Each unit mounted on a printed circuit board is described within the square enclosed by a bold dotted line on the circuit diagram.

- 1 . FM Front End, FM IF Amplifier, FM MPX Demodulator, AM Front End,
AM IF Amplifiermounted on PC board P100
- 2 . FM Sub-IF Amplifiermounted on PC board P200
- 3 . Phono Amplifiermounted on PC board P300
- 4 . Pre Amplifier, Tone Amplifier, and Main Amplifier
.....mounted on PC board P400
- 5 . Rectifiers and Power Supply Unitmounted on PC board P500

- 6 . Bass and Treble Control Unit, Loudness Control Unit, High and Low Filters Unit and Tape Monitor Switch.....mounted on PC board P600

2 . AM TUNER

2.1.Circuit Description

The AM tuner consists of two parts, a front end and an IF amplifier unit, both mounted on a part of PC board P100.

The front end is comprised of a converter and a diode. AM signals induced in the ferrite-rod antenna L001 are roughly selected in the antenna tuning circuit. The selected signals are applied to the base of converter transistor H114 through coupling capacitor C117. The converter forms a collector base self oscillating circuit and the local oscillation signal and the receiving signal are mixed at the base-emitter junction and converted into 455KHz intermediate frequency. The IF signal obtained from the collector of H114 is applied to the first IF transformer L113.

Diode H116, reverse-biased by resistors R113 and R114, eliminated signal overload distortion without sacrificing any receiving sensitivity.

The IF signal output is led to the IF amplifier consisting of two stages H115 and H106 which are shared with FM IF amplifier and amplified to high level. The amplified IF output is applied to diode H109 to detect audio signal. Then the detected audio signal is led to output pin J118 through filtering network. The DC component of the detected IF signal is used for AGC which affects the base bias current of H115. A part of IF signal output is also applied to diode H112 through capacitor C139 and rectified into DC current for energizing the tuning meter M001.

2.2.Suggestions for Trouble Shooting of AM Tuner

Symptom : No AM Reception

First, try to tune stations by rotating the flywheel tuning knob slowly and observe the tuning meter whether it deflects or not. If the tuning meter gives a deflection at

several frequencies received, no failure exists in the stages at least preceding IF transformer L115.

Next, connect an oscilloscope to tuner output pin J118 and check audio signal.

If the tuning meter does not deflect, check the local oscillator circuit. Normal oscillation voltage at the hot end of the oscillator capacitor is 2 to 3 volts, varying with tuning capacitor position. When measuring oscillation voltage use an RF VTVM, no circuit tester gives correct indication. If the local oscillation voltage is normal check all voltage distributions in the tuner circuit by using a circuit tester and compare the measured values with those shown in the schematic diagram.

3 . FM TUNER

3.1.Circuit Description

The FM section consists of four parts, FM front end, IF amplifier, MPX stereo demodulator, and Sub-IF amplifier.

FM signals induced by an FM antenna are led to FM antenna coil L101 through antenna attenuator switch S001 and balun coil L002. The signals are then applied to an FET RF amplifier and the amplified output is applied to mixer transistor H102 through a tuning circuit and converted into 10.7MHz IF signals. H103 is a local oscillator transistor. The undesired drain-to-gate interelectrode capacitance of RF amplifier H101 is neutralized by the secondary take up winding on L102 and capacitor C102 for maximum gain and good stability. The gate of H101 is returned to the AGC bus through R101 and a bypass capacitor C185. The AGC voltage is obtained by rectifying a part of the second stage IF amplifier. The local oscillator is a Colpitts oscillator, oscillation being produced by capacitors C114 and C113. Oscillator injection to the base of mixer transistor H102 is accomplished by C108 and C186. The converted IF signals are led to the IF amplifier unit consisting of three transistor amplifier

stages and one IC limiter. The FM IF amplifier shares its third stage transistor H106 with the AM IF amplifier. The fully amplified IF signal is then applied to FM discriminator transformer L109 and demodulated into audible signals.

The demodulated audio signals are then applied to the base of 19KHz pilot signal amplifier H117. This amplifier operates as an emitter follower for the audio signals and has no 'voltage' gain. The audio output is obtained from the emitter of H117 and applied to the center tap of 38KHz tuned transformer L119 through a 67KHz SCA trapping filter consisting of L120 and C159. The audio signals are split into right and left channel circuits by the diode-switching networks, then led to the crosstalk canceling amplifiers. When the demodulated audio signal is stereo composite signal, the 19KHz pilot signal amplifier operates as a tuned amplifier for the 19KHz pilot signal and as an emitter follower for the composite signal except 19KHz. The pilot signal, amplified by H117, is applied to H118 for further amplification. Then it is rectified by the full wave rectifier consisting of diodes H112 and H123, thus providing 38KHz pulsating current to drive 38KHz sub-carrier amplifier transistor H120, and 38KHz sub-carrier is obtained. The 38KHz sub-carrier and stereo composite signal, except 19KHz, are superimposed at the secondary coil of L119 and the composite signal is alternatively sampled by the right and left channel switching diodes at the rate of 38KHz. The sampled or separated outputs are led to the crosstalk canceling amplifier consisting of H128 and H129. Then led to tuner output pins J112 and J114 after canceling undesirable crosstalk. A tuned circuit, L121, and C172 is filtering circuit against 38KHz.

The model 28 is equipped with sub-FM IF amplifier consisting of a transistor amplifier stage and rectifiers for stereo-monophonic automatic switching over and driving of the tuning meter. The sub-FM IF amplifier obtains its input signal from the third FM IF amplifier stage through a small coupling capacitor C136 and amplifies

it. The amplified output is applied to diodes H202 and H203 for rectification into DC. The voltage developing across H203 is supplied to tuning meter M001 through resistors R204 and R205 and rotary switch S002-3. H202 provides its DC output to the base of H119 through R143 for stereo-monophonic automatic switching over operation.

The second 19KHz pilot signal amplifier H118 is so designed that the emitter circuit is electrically switched on and off by controlling the bias current of switching transistor H119. The bias current is obtained from the sub-IF amplifier circuit consisting of transistor H201, 10.7MHz IF transformer L201 and two diodes H202 and H203. The stereo switch on the front panel is connected across the base and emitter of switching transistor H119. Therefore, when the switch is in its normal "off" position, the base and emitter is short-circuited and no emitter current flows. Thus the emitter of the second 19KHz pilot signal amplifier is cut off and no 19KHz signal appears at the collector of H118. No stereo separation is obtained. When the stereo switch is depressed, the emitter-base short-circuit is opened and the rectified, by H202. DC current of a part of the sub-IF amplifier output flows into the base of H119. If the level of a received FM signal is higher than the pre-determined level, the DC current turns on the switching transistor H119 and H118 begins to operate. Providing the presence of 19KHz pilot signal under this circumstances, the full wave rectified DC component of the pilot signal developing across R146 provides the base bias current to tuner on 38KHz sub-carrier amplifier H120. As H120 is turned on, stereo beacon lamp switching transistor H121 whose base and emitter are connected across R169 in the emitter circuit of H120 turns on, too.

3.2. Suggestions for Trouble Shooting of FM Tuner

3.2.1. Symptom : No FM Reception

First, turn on the power switch and try to tune in to FM stations. Rotate flywheel

tuning knob slowly and observe the FM tuning meter. If the tuning meter deflects at several frequencies, the tuner circuit preceding the limiter circuit may have no failure. Tune the set to a station and check the following points by using a high sensitivity oscilloscope : output of the FM discriminator test point B, output of the 19KHz pilot signal amplifier test point H., and Multiplex stereo output pin J112 or J114. When no reading is observed on the tuning meter, check the local oscillator circuit by using an RF VTVM. Normal local oscillation voltage is about 1 volt at the hot end of the tank circuit. If the oscillation voltage is normal, check all voltage distributions and compare them with those shown in the schematic diagram.

3.2.2.Symptom : No Stereo Separation

First, check the stereo switch is depressed. Connect an FM RF signal modulated by a stereo signal to the FM antenna terminals and check whether the stereo beacon lamp is turned on or not. When the lamp is not turned on, connect an oscilloscope to test point G and observe 38KHz stereo sub-carrier is correctly generated or not.

4 . FM AND AM TUNER ALIGNMENT

The following alignment requires many precision measuring equipments shown in P. No alignment should be performed in the field unless the service man has these equipments and enough knowledge in solid state amplifier components, since all the units are factory aligned and not become misaligned by themselves.

4.1.AM Front End

- 1) Set an AM signal generator to 600KHz, 400Hz 30% modulation. Tune the receiver to the same frequency and adjust local oscillator coil L112 until the dial pointer coincides with the 600KHz marking on the dial.
- 2) Set the AM signal generator to 1400KHz. Tune the receiver to the same frequency

and adjust trimming capacitor C183-4 mounted on the tuning capacitor until the dial pointer coincides with the 1400KHz marking on the dial.

3) Repeat procedure 1 and 2 until no further adjustment is necessary between 600KHz and 1400KHz.

4) Set the generator to 600KHz. Tune the receiver to the same frequency and adjust antenna coil L001 in a plastic case for maximum output.

5) Set the generator to 1400KHz. Tune the receiver to the same frequency and adjust antenna trimming capacitor C183-3 mounted on the tuning capacitor for maximum output.

6) Repeat procedure 4 and 5 until no further improvement is obtained.

Note : During tracking alignment, reduce the signal generator output as necessary to avoid AGC action.

4.2.AM IF Amplifier

To align the AM IF amplifier, a sweep generator with 455KHz marker generator combined is necessary.

1) Connect the sweep generator across the AM local oscillator section of the tuning capacitor and common ground, connect an oscilloscope to test point C.

2) Turn each primary and secondary core of IF transformers L113,L114,and L115 for maximum and symmetrical response with the marker pip at the top.

4.3.FM Front End

4.3.1.Local Oscillator Adjustment

1) Measuring instruments connection

Connect an FM signal generator to the FM antenna terminals on the rear panel. Connect a VTVM or an oscilloscope across the speaker system terminals.

2) Set the FM signal generator to 90MHz, 400Hz 100% modulation. Tune the receiver to the same frequency and adjust local oscillator coil L104 until the dial pointer

coincides with the 90MHz marking on the dial.

3) Set the FM signal generator to 106MHz. Tune the receiver to the same frequency and adjust trimming capacitor C182 until the dial pointer coincides with the 106MHz marking on the dial.

4) Repeat procedure 2 and 3 until no further adjustment is necessary between 90MHz and 106MHz.

4.3.2.FM Tracking Alignment

1) Set an FM signal generator to provide about 5uV at 90MHz. Tune the receiver to the same frequency and turn each core of L101 and L102 for maximum output.

2) Set the FM signal generator to 106MHz. Tune the receiver to the same frequency and adjust trimming capacitors C183-1 and C183-2 for maximum output.

3) Repeat procedure 1 and 2 until no further improvement is obtained.

4.4.FM IF Amplifier

To align the FM IF amplifier, a high frequency sweep generator with 10.7MHz marker generator combined is required. Connect the sweep generator to test point D and an oscilloscope to test point A. Turn each primary and secondary core of IF transformers L105, L106, L107 and L108 for maximum and symmetrical response with the marker pip at the top.

4.5.FM Discriminator

Connect an oscilloscope to test point B and turn the primary and the secondary cores of discriminator transformer L109 for straight and symmetrical "S" curve with 10.7MHz marker pip at the center.

More precision adjustment of discriminator requires a distortion meter. To make this precision adjustment, connect an FM signal generator having low distortion characteristics to the antenna terminals of the set. Tune the set to the FM signal and measure the distortion of audio output. Turn the primary core of the discriminator transformer so as to obtain minimum distortion.

4.6.FM Sub-IF Amplifier

To align the sub-IF amplifier, tune the receiver to an FM signal and turn the core of L201 so that the FM tuning meter reads maximum deflection.

4.7.FM Stereo Demoduator

A stereo multiplex and RF FM signal generator is required to make the separation adjustment on this circuit.

Perform the following adjustment in sequence.

- 1) Set the FM signal generator to 98MHz, 2mV output level. Tune the receiver to the same frequency. Ensure that the stereo switch is depressed for stereo operation
- 2) Connect an oscilloscope probe to test point G and turn each core of L117, L118 and L119 for maximum 38KHz sub-carrier wave on the scope.
- 3) Turn the core of L119 again to obtain equal stereo separation in both of the right and left channels.
- 4) Adjust trimming resistor R175 for maximum and equal stereo separation in both channels.

5 . PHONO AMPLIFIER

A phono signal from the pickup is led to the phono amplifier for the RIAA equalization and pre-amplification. The phono amplifier makes use of two transistors H301 and H303. The collector of H301 is direct coupled to the base of H303 and the base bias for H301 is derived from the emitter circuit of H303. This configuration assures a good thermal and electrical stability. R309, R311, R305, C305 and C307 condition the feedback characteristic from the collector of H303 to the emitter of H301 for precise RIAA equalization. The RIAA equalized and amplified phono signal is led to selector switch S002-1 and S002-2.

6 . PRE-AMPLIFIER AND TONE AMPLIFIER

The audio signal selected by the selector switch S002-1 is led to the pre-amplifier through stereo switch S003, tape monitor switch S601-4 and the volume control with loudness control network. The signal is applied through coupling capacitor C401 and resistor R459 to the base of H401 which is an emitter follower to achieve low driving impedance for C-R tone control network. The signal obtained from the emitter of H401 is led to the tone control network through coupling capacitor C403. After bass and treble controlled by the tone control network, the signal is applied to the two stage tone amplifier consisting of H403 and H405. Negative feedback is utilized from the collector of H405 to the emitter of H403 through C409, R413 and R411 to maintain good stability and linearity.

7 . MAIN AMPLIFIER

7.1.Circuit Description

7.1.1.Amplifier

The amplified signal obtained from the collector of H405 is applied to the base of H407 via the balance control R017 and Hi and Low filter networks. The output of H407 is applied to the base of H409. H409 provides voltage amplification necessary to drive the driver transistors H411 and H413. These two transistors are operated in a complementary-symmetry configuration with their respective power transistors H001 and H002. The output of H411 is applied to the base of H001, and that of H413 to H002. Combined operation of PNP transistor H413 and NPN transistor H411 with NPN power transistors H001 and H002 provides a single-ended push-pull output. This output is applied to loudspeaker output terminals J003 through coupling capacitor C429 and headphones jack J004. To maintain overall stability and linearity, negative feedback is utilized throughout the amplifier. This feedback is also necessary to reduce distortion to be well under the specified limits.

R437 and R429 condition the feedback loop gain.

7.1.2. Dynamic Bias

Dynamic bias is applied to the bases of driver transistors H411 and H413. H411 and H413 determine the class of operation for the power amplifier transistors H001 and H002, respectively, thus maintaining a constant class of operation by establishing and maintaining proper collector-to-emitter current. This dynamic bias circuit consists of adjusting resistor R457 and temperature sensitive diodes H415, H417, and H419.

The circuit provides a variable base bias for driver transistors H411 and H413 and automatically maintains proper base voltage, bias condition, with temperature change.

7.1.3. Amplifier Protection

Protection for the amplifier is provided by two varistor diodes H421 and H423.

When a grossly overloading input signal is applied across the bases of driver transistors H411 and H413, these varistor diodes effectively clip the excessive voltage and protect the driver and output transistors against damage due to the overloading input signal.

In the other case of output short-circuit, the currents through H001 and H411 increase and it results in an increase of the emitter potential of H411. On the other hand, the base potential has been forced to a fixed value by varistor diode H421. Then the base-emitter biasing of H411 is decreased and the current flows through H411 and H001 are limited in safe operating condition.

7.2. DC Balance and Bias Adjustment of the Main Amplifier

7.2.1. DC Balance Adjustment

Connect an oscilloscope and a dummy load (8 ohms) across the speaker system output terminals for the channel being tested and an audio oscillator (1000Hz) to the AUX jack on the rear panel.

Set the selector switch in the AUX, the bass, treble and balance controls flat or center position, the loudness, hi filter and low filter switches off and the volume control maximum. Turn the bias control resistor R457 fully clockwise. Adjust DC balance control R455 until equal clipping level is obtained for both polarities. Repeat the same procedure for the other channel.

Note : During DC balance adjustment, adjust the output level of the audio oscillator to show the clipping level on the scope precisely.

7.2.2. Bias Adjustment

Give no input signal and connect a VTVM across resistor R447 or R449. Adjust the bias control resistor R457 until the VTVM reads 5mV. Ensure no crossover distortion is observed on the scope with a faint signal input from an audio oscillator. To adjust the other channel, connect the VTVM across resistor R448 or R450 and adjust bias control resistor R458 for the same voltage reading.

Note : PC board P400 on which bias control resistor R457 and R458 are mounted is located in back of the power transistors.

7.3. Suggestions for Trouble Shooting of Power Amplifier

7.3 1. Excessive Line Consumption

- 1) Check for shorted rectifiers H502, H503, H504, H505, H506, H507 and H508, also check C501, C503 and C507.
- 2) Check for shorted transistors H411 and H413. Check for open control resistor R457 and bias diodes H415, H417 and H419.
- 3) Check L003 for short.

CAUTION : Because the driver and output stages are direct coupled, components may fail as a direct result of an initial component failure. If a shorted or open transistor, diode, or control resistor is found be sure to check the

remaining driver and output components for short or open circuits before re-energizing the amplifier.

7.3.2.No Line Consumption or Zero Bias

- 1) Check line cord, over current circuit breaker, and bias diodes H415, H417 and H419.
- 2) Check for open rectifiers H505, H506, H507 and H508, or open L003

8 . POWER SUPPLY UNIT

The power supply unit provides three different DC outputs of +38V, -11V and -2V.

+38V output is obtained by bridge connected rectifiers H505, H506, H507 and H508, and filtering capacitor C503. This source energizes the audio section.

Two rectifiers H503 and H504 are engaged in the rectification for -11V output. This output is well regulated by zener diode H501 and concerns with the tuner section.

The power supply unit has another DC output of -2V for stereo beacon lamp operation.

9 . TEST EQUIPMENTS FOR SERVICING

Item	Manufacturer and Model No.	Use
AM Signal Generator		Signal source for AM Alignment
Test Loop		Used with AM Signal Generator
FM Signal Generator	Distortion 0.3% or less	Signal source for FM Alignment
Audio Oscillator	Residual distortion 0.02% or less	Sine wave source for modulating AM or FM Signal Generator, or trouble shooting
Stereo Modulator	Distortion 0.3% or less	For Separation Alignment and trouble shooting
Oscilloscope	High sensitivity	Wave form analysis and trouble shooting
VTVM	With RF probe	Trouble shooting
Circuit Tester		Trouble shooting
Sweep Generator	For 455KHz and 10.7MHz	AM and FM IF Alignment
8-ohm Resistors	0.5% 50W (non-inductive)	Dummy Load
Line Voltmeter	0.....150V AC	To monitor the line voltage
Variable Auto Transformer	0.....140V, 10A	To adjust the primary power voltage
