Handling Precautions for MOS ICs

Generally, the insulation resistance of the oxide layer in MOS IC structures is very high, and the oxide layer is very thin. Because of this, it is possible that the static voltages usually present on clothes and the human body will be enough to generate a potential difference across the insulator, high enough to cause a breakdown of the insulating layer.

The following precautions should be taken while handling these ICs.

(Particular care should be taken under conditions of low humidity.)

Precautions in Replacing MOS ICs

1. Store new ICs by inserting them into a urethane-polyester cushion (which is somewhat conductive), or wrapping it in aluminum foil, so that all the pins are at the same potential.
   (The ICs should be stored in that manner until mounted on the circuit board.)

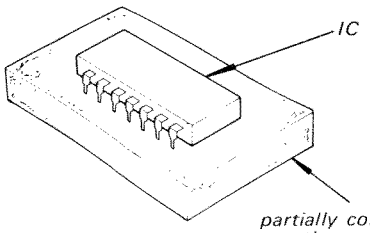

Fig. A

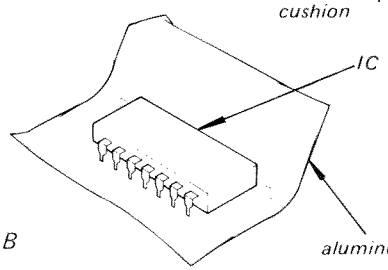

Fig. B

2. Check the soldering iron for possible power-line leakage current. Make sure that there is no leakage path by connecting an ohmmeter to the tip of the soldering iron and the plug as shown in Fig. C. If there is a leakage path, use some other soldering iron.

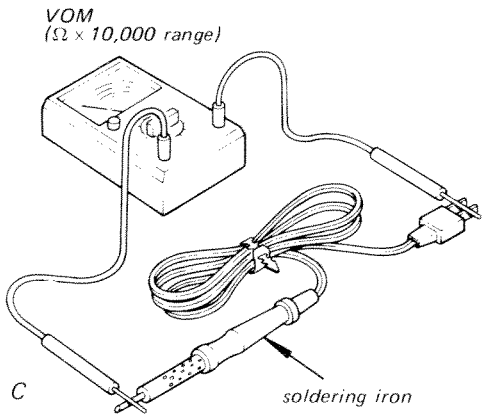

Fig. C

3. Equalize any potential difference between the clothes, the tools in use, the work bench, the set being worked on, and the packaged IC by touching them all in succession with the hands or a conductive wire or tool.

4. The following are effective methods for handling ICs that remove the potential difference across the oxide layer.
   - Use a paper clip modified by soldering in a wire braid insert.

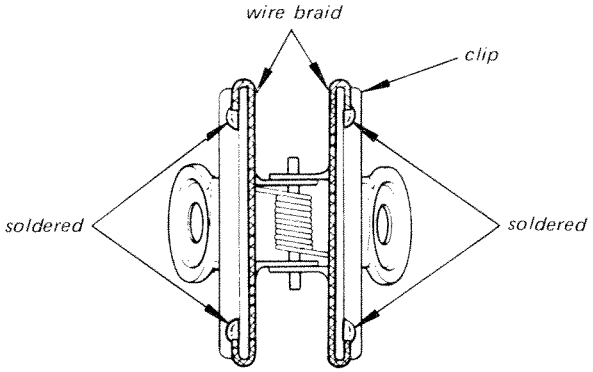

Fig. D Make sure that there is no solder on the inside.

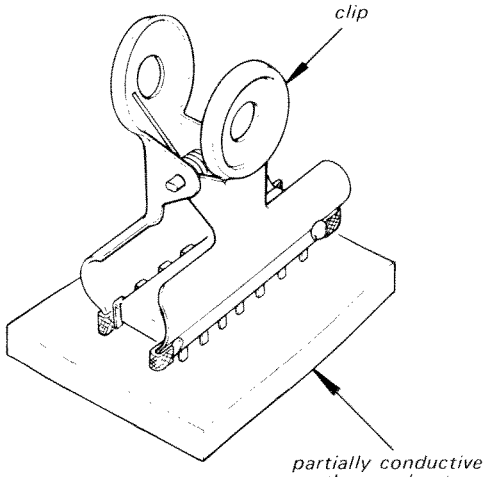

Fig. E

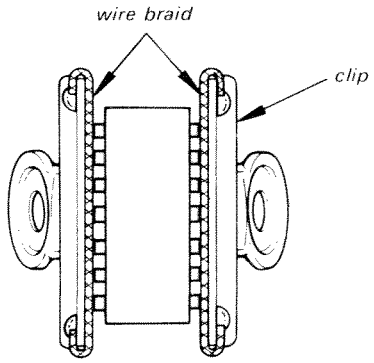

Fig. F Make sure that all the pins are in contact with the wire braid (all the pins will then be at the same potential.).

- Take a short length of fine bare wire and wind it around the IC so that it shorts all the pins of the IC, while it is still in the urethane-polyester cushion or aluminum foil. This ensures that all the pins are at the same potential.

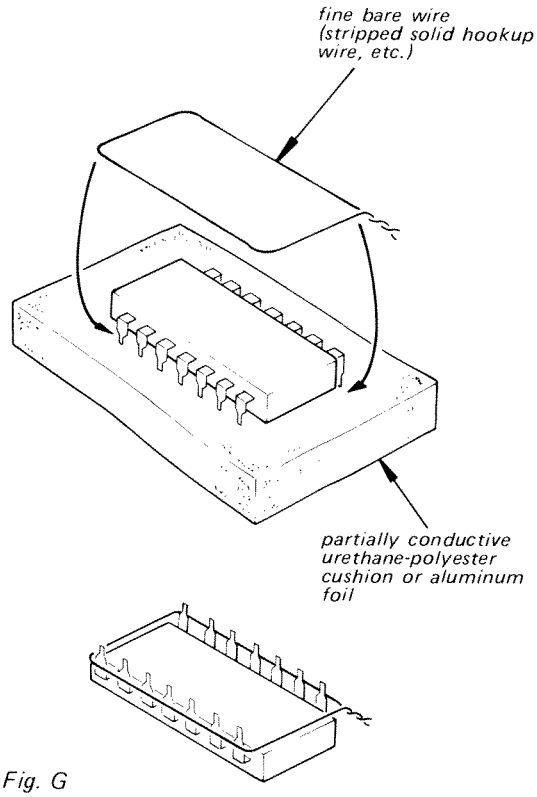

Fig. G

- When it is necessary to handle the IC with the fingers, do not touch any pin, and hold the IC at the ends of its plastic-package case as shown in Fig. H.

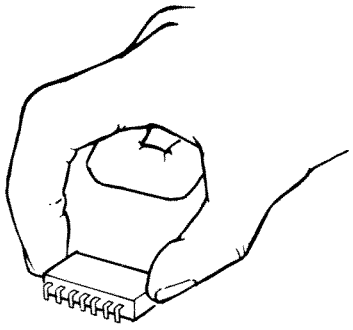

Fig. H

5. Method of Mounting
Insert the IC while holding it with the modified clip, and solder all the pins with the clip still shorting the pins. (Similarly, solder all the pins while the bare shorting wire is still wound around them.). Remove the clip or the bare shorting wire only after all the pins have been soldered.

Precaution while Checking C-MOS ICs

The C-MOS ICs (Complementary MOS) are MOS ICs that have their output sections made up of N-channel and P-channel push-pull stages to increase their speed of operation. If the output terminal of these ICs comes into contact with B+ or B- voltage, then the FET which is ON at that time will either become shorted or open.

This is valid for all the output sections that are connected together by the interconnections. Even the circuits that are physically separated (and not on the same board) can be destroyed simultaneously.

Example:

SECTION 1
OUTLINE

1-1. CIRCUIT OPERATION

This set is equipped with an LED peak program meter, which indicates the input signal level (as a bar graph).

The following explanations describe the operation of each of the circuit.

1. IC601 Input Circuit

Input signal Ⓐ (waveform Ⓐ) is amplified by Q107 and is applied to IC103 in the LOG converter circuit. By the characteristic of a diode, the input signal is logarithmically compressed and waveform Ⓐ changes into waveform Ⓑ.

The peak of signal Ⓑ is detected by D105 and smoothed by C130, Then it is applied to terminal (11) of IC601 as dc voltage (waveform Ⓒ). Q109 controls the input current which is applied to IC601.

2. LED Indication Circuit

The LEDs turn on when the anode signals (Ⓓ – Ⓖ) and the cathode signals (Ⓗ – Ⓞ) drop to a LOW level at the same time.

ex) LINE OUT output –5dB

Ⓓ, Ⓕ : LOW level

↓

waveform Ⓗ – Ⓞ : anode, cathode: LOW level

↓

L–CH/R–CH : LEDs 1~8 turn on

Ⓞ	8	16	8	16

Diagram 1.

(When either two of the signals Ⓓ – Ⓖ and of Ⓗ – Ⓞ drop to LOW level, the LEDs shown in the diagram turn on.)

3. Peak Hold Reset Circuit

1) Mode: S7 [AUTO]

The trigger pulse generated by Q601 (PUT=Programmable Unijunction Transistor) is applied to the base of Q602. The reset signal is applied to the reset terminal (12) of IC601 at intervals of 2.25 seconds and the peak level is reset.

2) Mode: S7 [MANUAL]

When the MANUAL switch is turned on, B+ voltage is applied to the base of Q602. Then reset terminal (12) of IC601 drops to a LOW level and the peak level is reset.
