## Read These Instructions With Extreme Care Before Attempting Alignment.

**CHASSIS:** Turn the station selectors completely counter-clockwise, without forcing. Dial pointer should be at zero mark on logging scale. If not, reset the dial pointer. Disconnect the external antennas and the AM antenna link. Swing AM Ferrite Loop antenna rearward to operating position. When using an oscilloscope for alignment, set the output level controls for no overload, as shown by the proper waveform shape. Set FM Antenna switch to NORMAL.

**SIGNAL GENERATORS:** The signal generator equipment must be able to supply the following: FM RF 22.5 KC deviation at 400 cps; AM RF modulated 30% at 400 cps; AM IF with 30 KC sweep for AM bandwidth adjustment; audio oscillator accurately calibrated for 1 and 10 KC audio output for testing the 10 KC AM whistle filter.

**MEASURING INSTRUMENTS:** DC VTVM, AC VTVM, and scope for alignment.

**ALIGNMENT:** Allow the chassis and test instruments to warm up for at least fifteen minutes. Adjust the line voltage for 117 volts AC, 50-60 cycles. Use fully insulated tools; a small screwdriver for all trimming capacitors; a K-tran tool for Z1, Z2, Z3, Z4, Z5 and Z6; a hex tool for Z7, Z8, Z9, L2, L3, L5, L6, L8, L9 and L14.

### NOTES:

- 1 — For AM alignment short out C91.
- 2 — For calibrating both the AM and FM-RF, use as low an output voltage as possible from your signal generator.
- 3 — Decrease FM signal generator output while adjusting FM-IF transformers so that DC VTVM shows noted voltage.
- 4 — The center frequency should be kept constant for FM-IF, limiter and ratio detector alignment.
- 5 — If adjustment of muting oscillator is necessary, adjust it for 3 MC with a Grid-dip Meter.

**NOTE:** The above procedure is based on the use of the FISHER Model 300 Multiplex Generator.

1 — In steps 2 through 11, the audio output of the Multiplex Generator should be connected to lug 1 of the multiplex sub-chassis through a 12,000 ohm, ½-watt, carbon resistor, and a 180 uuf capacitor should be connected between lug 1 and ground. The wiring from the MPX TEST jack on the main chassis to lug 1 must be disconnected during Steps 2 through 11.

2 — The vertical amplitude of the Lissajous pattern will increase slightly

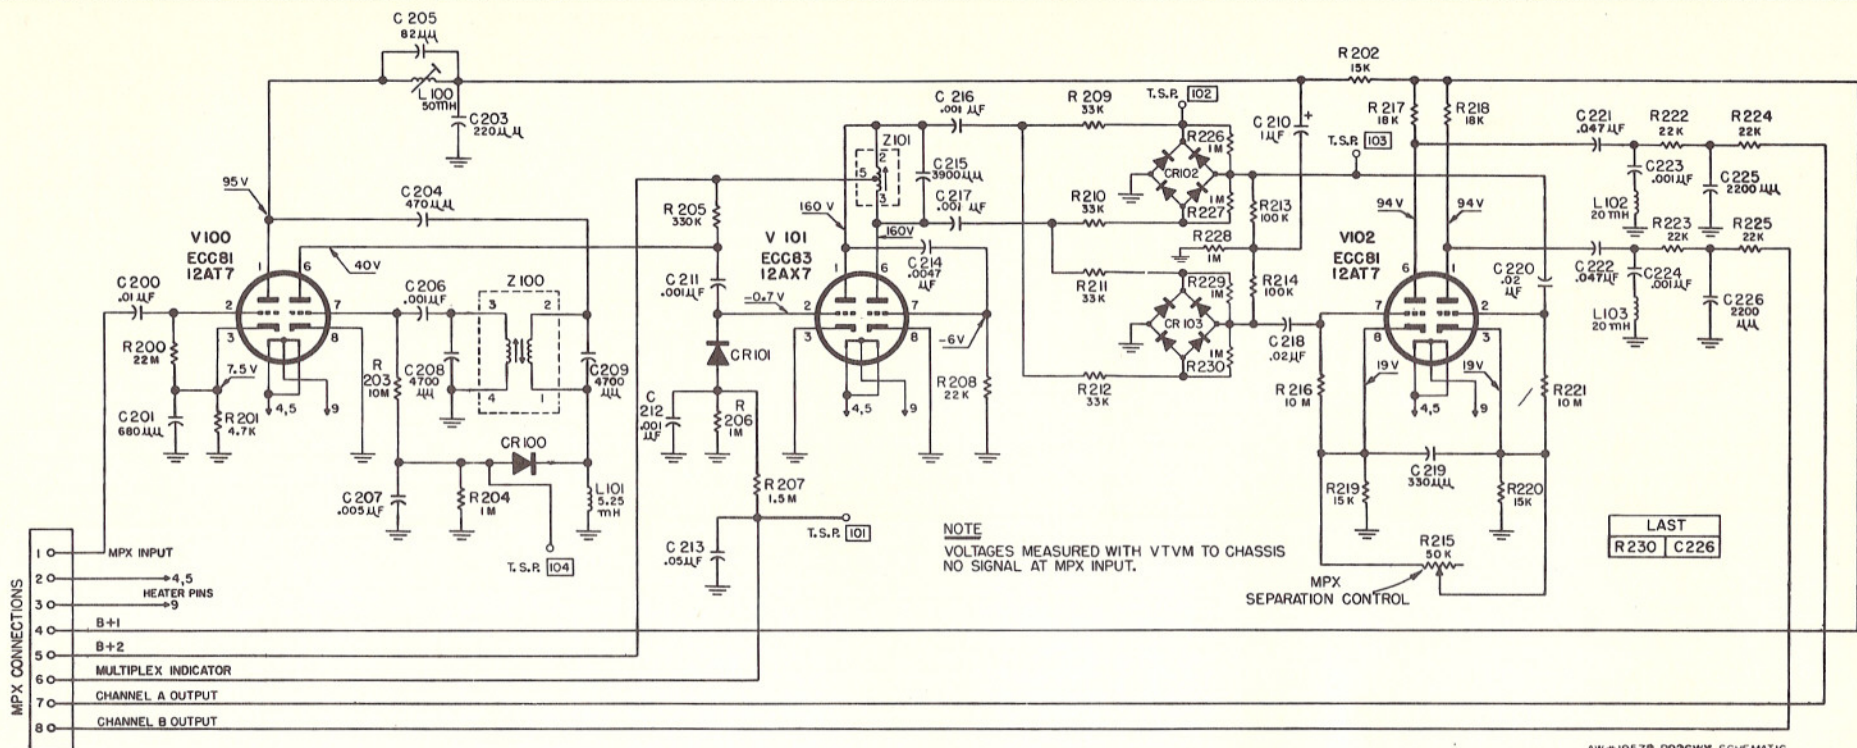

as the generator output is increased. This is a normal occurrence.

3 — If DC VTVM reading falls below —9 volts when maximum reading is obtained on the AC VTVM, readjust bottom of Z100, then repeat Step 5. Repeat this procedure until maximum AC VTVM reading is obtained with DC VTVM reading greater than —9 volts.

4 — Tune the FISHER to the RF output frequency of the Multiplex Generator.
